

Effects of semaglutide on chronic kidney disease in patients with type 2 diabetes

Efecto de semaglutide sobre la enfermedad renal crónica en pacientes con diabetes mellitus tipo 2

Dear Editor, we would like to congratulate Dr. Perkovic and colleagues demonstrating that semaglutide reduced by 24% the risk of kidney outcomes and death from cardiovascular causes in persons with type 2 diabetes (T2D) and chronic kidney disease (CKD)¹. In SUSTAIN 6, semaglutide showed renal benefits mainly in terms of albuminuria reduction, interestingly the metabolic effects (blood sugar control and body weight) were higher in the 1 mg dose as compared to 0.5 mg². In concordance, in the SUSTAIN FORTE, the 2 mg weekly dose was also better in metabolic control³, indicating that the effect is in part dose-dependent. In addition, when studying kidney function Shaman et al. found that 1 mg of semaglutide has a higher effect in reducing albuminuria and delaying glomerular filtration rate progression as compared to liraglutide 1.8 mgs/day and low semaglutide dose 0.5 mgs/weekly⁴. The SELECT trial clearly demonstrated renal benefit of 2.4 mgs/weekly semaglutide in obese persons without diabetes⁵. Although the results of FLOW study are impressive, we are wondering if the beneficial effects could be in part dose-dependent. By now, FLOW trial

demonstrated that semaglutide is a cardiorenal protective drug in patients with T2D and CKD, but it is not known if the higher doses used in persons with obesity may exert better renal benefits in comparison to the doses used in patients with T2D.

Conflicts of interest
